CS 61 - Programming Assignment 5

Objective

The purpose of this final programming assignment is to test the limits of your LC3 skill by giving you a challenging implementation problem straight out of the textbook.

High Level Description

There is a server somewhere, called the Busyness Server. This server tracks whether 16 different machines connected to it are **busy (0)** or **free (1)**: this information is stored in a single LC-3 word (aka a "bit-vector").
You will write a menu-driven system that allows the user to query this bit-vector as to the availability of the 16 machines, in various combinations.

Before You Start Coding

This assignment is based on a variation of Question 9.9 (p. 242 of the textbook) – which will require that you first work through the following:
- Example 2.11   (p. 37)
- Question 2.36   (p. 46)
- Question 5.6   (p. 146)

(<u>Note:</u> I have lightly edited the wording of the following excerpts from the text for increased clarity)
<u>Example 2.11</u>

Suppose we have eight machines that we want to monitor with respect to their availability. We can keep track of them with an 8-bit BUSYNESS vector, where a bit is 1 if the unit is free, and 0 if the unit is busy. The bits are labeled 0 through 7, from right (lsb) to left (msb).

So for example, the BUSYNESS bit vector 11000010 corresponds to the situation where only units 7, 6, and 1 are free, and therefore available for new work assignment.

Suppose work is assigned to unit 7. We update our BUSYNESS bit vector by performing the logical AND, where our two operands are the current bit vector 11000010 and the bit mask 01111111. The purpose of the bit mask is to clear *(set to 0)* bit 7 of the BUSYNESS bit vector, without affecting the remaining 7 bits. The result is the bit vector 01000010, which replaces the previous BUSYNESS.

Recall that we encountered the concept of bit mask in Example 2.7. Recall that a bit mask enables one to interact with some bits of a binary pattern while ignoring the rest. In this case, the bit mask <u>clears</u> bit 7 and <u>leaves unchanged</u> (ignores) bits 6 through 0.

Suppose unit 5 finishes its task and becomes idle. We can update the BUSYNESS bit vector by performing the logical OR of it with the bit mask 00100000. The result is 01100010, which again replaces the previous BUSYNESS.

Question 2.36

Refer to Example 2.11 (above) for the following questions.

   A. What bit mask value and what operation would one use to set machine 2 from <u>free</u> (1) to <u>busy</u> (0)?   *(Without changing the state of the other machines, obviously!)*
   B. What bit mask value and what operation would one use to set machines 2 and 6 to <u>free</u> (1)? *(Again, without changing the state of the other machines).*
     Note: This can be done with a single <u>boolean operation</u>, but it cannot be implemented in LC-3 assembly language with a <u>single instruction</u>!
   C. What bit mask value and what operation would one use to set **all** machines to <u>busy</u> (0)?
   D. What bit mask value and what operation would one use to set **all** machines to <u>free</u> (1)?
   E. Develop a procedure to "interrogate" the status of machine 2 by isolating it as the "sign bit" (i.e. the msb).
     For example, if the BUSYNESS pattern is 0101 1100, then the output of this procedure is 10000000. If the BUSYNESS pattern is 0111 0011, then the output is 0110 0000. In general, if the BUSYNESS pattern is:

b7	b6	b5	b4	b3	b2	b1	b0

the output is

b2	b1	b0	0	0	0	0	0

Hint: What happens when you ADD a bit pattern to itself?

Question 5.6

Recall the machine busy example from Section 2.7.1. Assuming the BUSYNESS bit vector is stored in R2, we can use the LC3 instruction AND R3, R2, #1 to determine whether machine 0 is busy or not. If the result of this instruction is 0, then machine 0 is busy.

   A. Write an LC3 instruction that determines whether <u>machine 2</u> is busy.
   B. Write an LC3 instruction that determines whether <u>both</u> machines 2 and 3 are busy.
   C. Write an LC3 instruction that indicates whether <u>none</u> of the machines are busy.
   D. Can you write a single LC3 instruction that determines whether machine 6 is busy? Is there a problem here?

The variation of <u>Question 9.9</u> that you will implement in this assignment:
(remember - 0 = busy; 1 = free)
   A. Check if <u>all</u> machines are busy; return 1 if all are busy (0), 0 otherwise (i.e. if *any* are free).
   B. Check if <u>all</u> machines are free; return 1 if all are free (1), 0 otherwise (i.e. if *any* are busy).
   C. Check <u>*how many*</u> machines are busy (0); return the number of busy machines.
   D. Check <u>*how many*</u> machines are free (1); return the number of free machines.
   E. Check the <u>*status*</u> of a specific machine whose number is passed as an argument in R1; return 1 if that machine is free (1), 0 if it is busy (0).
   F. Return the <u>*number*</u> of the first (lowest numbered, or rightmost) machine that is free (1) - i.e. a number between 0 and 15.   **If no machine is free, return -1** *(= xFFFF)*
     e.g. if the busyness vector is 0101 0100, then the first available machine is #2
     (Remember - <u>the lsb is always considered bit 0</u>)

Your Tasks

The assignment can be broken down into the following tasks:

1. Your main code block should call a MENU subroutine, which prints out a fancy looking menu with numerical options, invites the user to input a choice, and returns in **R1** the user's selection {1, 2, 3, 4, 5, 6, 7} If the user inputs a non-existent option, output an error message and re-print the menu; repeat until a valid entry is obtained. In other words, there is no way of getting out of the subroutine with anything other than a number in the correct range.
   Here is the menu that you will be using for the assignment:
   *(it is given to you in the starter code as a single long string located at memory address **x6A00)***

   ```
   ***********************
   * The Busyness Server *
   ***********************
   1. Check to see whether all machines are busy
   2. Check to see whether all machines are free
   3. Report the number of busy machines
   4. Report the number of free machines
   5. Report the status of machine n
   6. Report the number of the first available machine
   7. Quit
   ```

2. Write the following corresponding subroutines:
   A. MENU
   B. ALL_MACHINES_BUSY
   C. ALL_MACHINES_FREE
   D. NUM_BUSY_MACHINES
   E. NUM_FREE_MACHINES
   F. MACHINE_STATUS
   G. FIRST_FREE

   plus the two helper subroutines:
   GET_MACHINE_NUM
   PRINT_NUM

===

Subroutine Headers

The following headers have been provided to you in the template - you must adhere to them exactly!

NOTE: Subroutine"parameters" are passed in R1.
Return values use either R1 (when the return is to be used as an input for a subsequent sub); or R2.

```
;-------------------------------------------------------------------------------------------------
; Subroutine: MENU
; Inputs: None
; Postcondition: The subroutine has printed out a menu with numerical options, invited the
;          user to select an option, and returned the selected option.
; Return Value (R1): The option selected:  #1, #2, #3, #4, #5, #6 or #7 (as a number, not a character)
;              no other return value is valid.
;-------------------------------------------------------------------------------------------------

;-------------------------------------------------------------------------------------------------
; Subroutine: ALL_MACHINES_BUSY (#1)
; Inputs: None
; Postcondition: The subroutine has returned a value indicating whether all machines are busy
; Return value (R2): 1 if all machines are busy, 0 otherwise
;-------------------------------------------------------------------------------------------------

;-------------------------------------------------------------------------------------------------
; Subroutine: ALL_MACHINES_FREE (#2)
; Inputs: None
; Postcondition: The subroutine has returned a value indicating whether all machines are free
; Return value (R2): 1 if all machines are free, 0 otherwise
;-------------------------------------------------------------------------------------------------

;-------------------------------------------------------------------------------------------------
; Subroutine: NUM_BUSY_MACHINES (#3)
; Inputs: None
; Postcondition: The subroutine has returned the number of busy machines.
; Return Value (R1): The number of machines that are busy (0)
;-------------------------------------------------------------------------------------------------

;-------------------------------------------------------------------------------------------------
; Subroutine: NUM_FREE_MACHINES (#4)
; Inputs: None
; Postcondition: The subroutine has returned the number of free machines
; Return Value (R1): The number of machines that are free (1)
;-------------------------------------------------------------------------------------------------

;-------------------------------------------------------------------------------------------------
; Subroutine: MACHINE_STATUS (#5)
; Input (R1): Which machine to check, guaranteed in range {0,15}
; Postcondition: The subroutine has returned a value indicating whether
;          the selected machine (R1) is busy or not.
; Return Value (R2): 0 if machine (R1) is busy, 1 if it is free
;          (R1) unchanged
;-------------------------------------------------------------------------------------------------
```

;---
; Subroutine: FIRST_FREE (#6)
; Inputs: None
; Postcondition: The subroutine has returned a value indicating the lowest numbered free machine
; Return Value (R2): the number of the free machine
;---

Helper subroutines (i.e. not selectable from menu)
Both subroutines are required for Option 5 (MACHINE_STATUS);
PRINT_NUM is required also for Options 3, 4 and 6
;---
; Subroutine: GET_MACHINE_NUM
; Inputs: None
; Postcondition: The number entered by the user at the keyboard has been converted into binary,
;   and stored in R1. The number has been validated to be in the range {0,15}
; Return Value (R1): The binary equivalent of the numeric keyboard entry
; NOTE: You can use your code from assignment 4 for this subroutine, changing the prompt,
;   and with the addition of validation to restrict acceptable values to the range {0,15}
;---

Your assignment 4 code is kind of overkill for this purpose, as it accepts & converts to binary all possible numbers in range {-32768, +32767}, while we only want {0, 15}
However, the code is already written & tested, so you may find it simpler to just package it as a subroutine and modify it a bit for the new purpose:

Required changes to your assn 4 code for GET_MACHINE_NUM sub:

- The binary value must be returned in **R1**, rather than the register specified for assn 4
- The prompt and error messages in assn 4 were provided as *remote* data, requiring the use of pointers to access them.
  You must substitute these with the new prompt & error messages, which are provided in the starter code as *local* data.
  So in assn 4 you would probably have set up the string output like this:
  ```
  LD R0, msg_pointer  ; msg_pointer stores remote address of message string
  ```
  In this subroutine version make sure you change that to:
  ```
  LEA R0, msg_label   ; msg_label is start of local message string
  ```
- Treat an initial '-' sign as an invalid input, exactly as you would a non-numeric input
  NOTE: *This is different from the behavior depicted in sample screen 9 below, which shows user entry "-14": this spec **requires** that the '-' sign* <u>immediately</u> *trigger the error handler.*
- After successfully converting the user input number, you must test that it is <= 15 (you already know that it is >=0, because you rejected negative inputs).
  If the the number is >15, it is invalid, so start over.

```
;-------------------------------------------------------------------------------------------------------
; Subroutine: PRINT_NUM
; Inputs: R1, which is guaranteed to be in range {0,15}
; Postcondition: The subroutine has output the number in R1 as a decimal ascii string,
; WITHOUT leading 0's, a leading sign, or a trailing newline.
;     Note: that number is guaranteed to be in the range {#0, #15},
;          i.e. either a single digit, or '1' followed by a single digit.
; Return Value: None; the value in R1 is unchanged
;-------------------------------------------------------------------------------------------------------
```
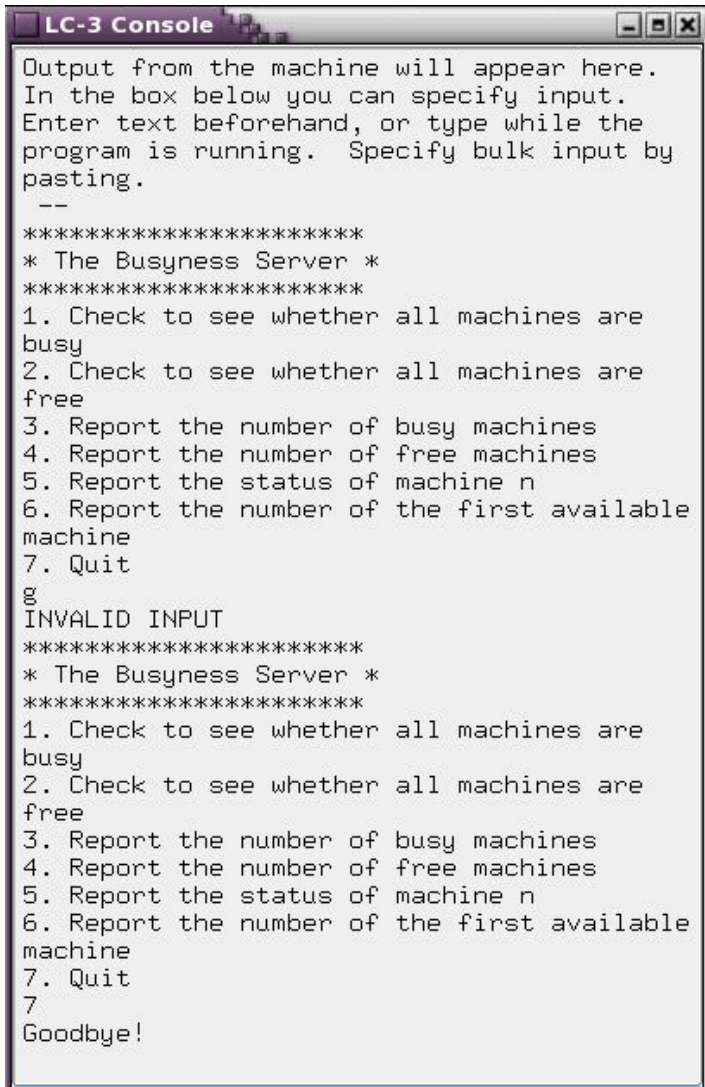

- Do **NOT** output a newline after the number output, as it may be part of a larger message.
- if n < 10, it is a single digit, and can be output as ascii by just adding x30
- if n >= 10, it is a 2-digit number: the first digit is '1', and the second digit is (n-10)
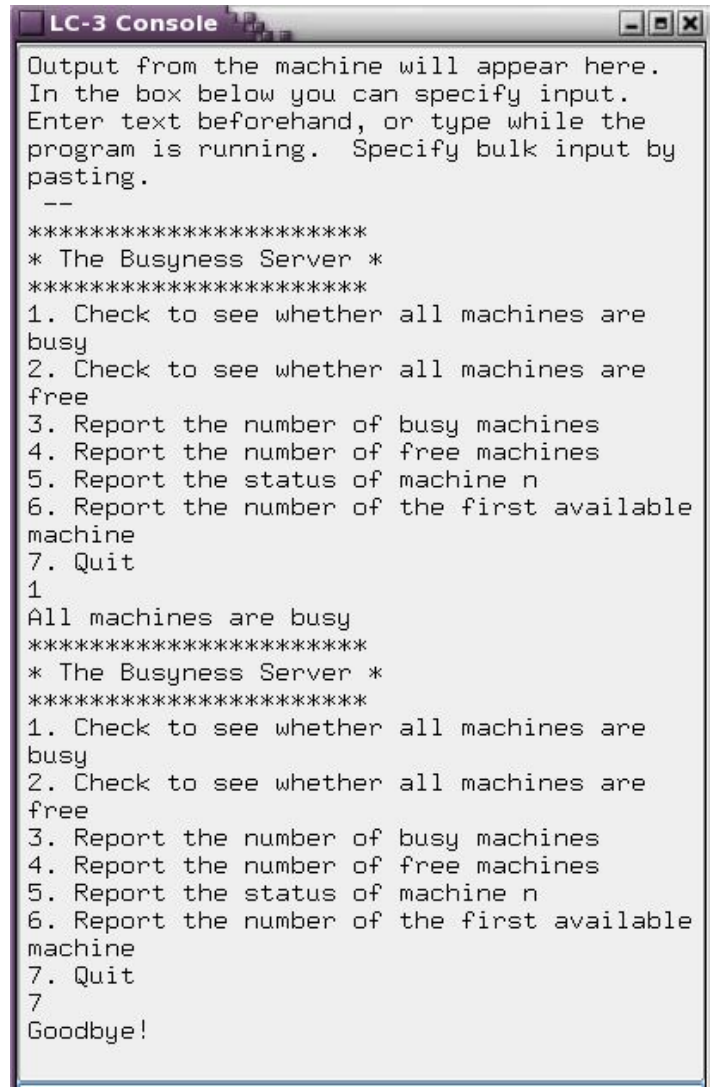

Expected/ Sample output

Output

- The caption for each sample screen lists the corresponding menu selection & value of the test busyness vector
- Note the placing of newlines in the output!

Examples

```

11. Option 6, BUSYNESS = x0000   12. Option 6, BUSYNESS = xABCD

Notes:
- As always, you must echo <u>all</u> inputs (no "ghost writing").
- When an invalid input is detected: Output the error message and re-prompt the user for input
- ***all outputs must be newline terminated***
  (<u>except</u> the number in the PRINT_NUM sub, which may be internal to a larger message)

Your code will obviously be tested with a range of different busyness vectors: Make sure you do likewise!

Uh...help?

No individual component of this assignment is really difficult - but it has a lot of "moving parts" that all have to work together properly, so it can be _very_ challenging, and take a _long_ time to complete! So we'll give you some hints :)

Really, Really Important

- **1 means free; 0 means busy**
- Store the BUSYNESS vector at the memory address **given to you in the template.**
  - The grader will test different values using this address
- Several of your subroutines require input validation: make sure that there is no way to exit such a subroutine except by providing valid input - in other words, if the user messes up, the subroutine must start over, with all prompts _(see e.g. the three Option 5 samples above)_

Hint 1
All the subroutine headers have been provided in the starter code, along with all prompts and error messages. Use the headers as a guide to the construction of your subroutines.
In particular, detailed guides for the two helper functions are provided with their headers above.
DO NOT ALTER ANY STRINGS OR ADDRESSES PROVIDED IN YOUR STARTER CODE!

Hint 2
NEVER backup (store/reload) the register used to return a value!
In all subroutines, R1 is used to return a numeric or character value; R2 is used to return a flag value
AWAYS backup R0 and R7 if your subroutine invokes any Traps; plus all registers used as temporary storage in the course of the subroutine.

Hint 3
Remember the algorithm you created to print out a number in binary: you examined each individual bit of a 16-bit register by "shifting" each bit into the msb in turn.
You will be using this same technique in several of your subroutines in this assignment.

Hint 4 – sub A (MENU)
This subroutine gets a **single** character from the user. You do **NOT** have to press enter for the character to be accepted. The moment the user enters a character, it will be echoed, and the subroutine will try to validate the input {'1', '7'}; if valid, the option value will be returned in R1; if not, an error message should be output and the prompt repeated (i.e. start over).
Should you return the menu option as an ascii numeric digit, or as the corresponding number?
Either can be made to work, but which do you think is easier to test after return to main?

After responding to any menu selection other than #7, the menu must be re-presented, in an infinite loop _(see pseudo-code at end)._
The only way to exit the loop is by selecting menu option 7 ("Goodbye").

Hint 5 – subs B & C (ALL BUSY/ALL FREE?)
If a machine is free, then it is NOT busy. If a machine is busy, then it is NOT free - i.e. you can use the exact same code structure for these two subroutines.
In both cases, return flag R2 = 1 for "affirmative" (all machines _are_ busy/free respectively).

Hint 6 – subs D & E (HOW MANY BUSY/FREE?)
These two subroutines form a pair like subs B & C above - you can use the same logic for both.

Hint 7 – sub F (MACHINE STATUS)
The first step is to obtain user input by invoking the helper subroutine GET_MACHINE_NUM
This will return a *validated* number from 0 to 15 in R1, to be passed directly to subroutine F.
The same number is also passed, still in R1, to the other helper subroutine PRINT_NUM when printing the full status report.
The only acceptable return values from GET_MACHINE_NUM are in the range **{0, 15}.**

Examples of valid input:
(sub returns with value in R1)
- 12
- 0
- 0003
- +4

Examples of invalid input:
*(error message, repeat prompt)*
- -12
- 16
- +2g
- g

See also the guide provided with the helper subroutine headers above.

Machine numbers for subroutine F:
The FIRST machine is machine 0 *(the lsb, or rightmost bit)*;
the LAST machine is machine 15 *(the msb, or leftmost digit)*

Machine IDs:

```
MSB                                             LSB
 |                                               |
[15 14 13 12]  [11,10,9,8] [7,6,5,4] [3,2,1,0]
```

Subroutine F can assume that the value in R1 has been properly validated {0, 15}
If machine (R1) is busy, return flag R2 = 0; if it is free, return R2 = 1

Hint 8 – sub G (FIRST_FREE)
As for sub F: the "lowest numbered" machine is the rightmost bit, aka the lsb, aka bit 0

To implement your menu-driven system, construct an <u>infinite loop</u> that works like this:

NOTE: Print (R1) means invoke PRINT_NUM(R1)

If you needed to print the contents of a different register, you would have to R1 <= Rx first.

```
while( true )
{
  R1 = menu()                    ; call MENU subroutine

  if (R1 == 1)
    R2 = all_machines_busy()       ; call ALL_MACHINES_BUSY subroutine
    if (R2 == 1)
      Print "All machines are busy\n"
    else
      Print "Not all machines are busy\n"

  else if (choice == 2)
    [similar]

  else if (choice == 3)
    R1 = num_busy_machines()       ; call NUM_BUSY_MACHINES subroutine
    Print "There are ", (R1), " machines busy\n"

  else if (choice == 4)
    [similar]

  else if (choice == 5)
    R1 = get_machine_number()      ; validated user entry from #0 to #15
    R2 = machine_status(R1)        ; call MACHINE_STATUS and pass in R1
    if (R2 == 1)
      Print "Machine ", (R1), " is free\n"
    else
      Print "Machine ", (R1), " is busy\n"

  else if (choice == 6)
    R1 = first_machine_free()      ; call FIRST_FREE subroutine
    if (R1 == -1 )                 ; #-1 == xFFFF
      Print "No machines are free"
    else
      Print "The first available machine is number ", (R1), '\n'
                ; don't forget to terminate this o/p with a nl!
                ; all other messages have their terminal nl built in.

  else if (choice == 7)
    Print "Goodbye!\n"
    HALT
}
```

Submission Instructions
 Submit ("Upload") your **assignment5.asm** file *(and ONLY that file!)* to the Programming Assignment
 5 folder in Gradescope: the Autograder will run & report your grade within a minute or so.
 You may submit as many times as you like - your grade will be that of your last submission.
 If you wish to set your grade to a previous submission with a higher score, you may open your
 "Submission history" and "Activate" any other submission - that's the one we will see.

Rubric
- To pass the assignment, you need a score of >= 80%.
  The autograder will run several tests on your code, and assign a grade for each.
  But certain errors *(run-time errors, incorrect usage of I/O routines, missing newlines, etc.)* may
  cause ALL tests to fail => 0/100! So submit early and study the autograder report carefully!!

- **You must use the template we provide** - if you make <u>any</u> changes to the provided starter code,
  the autograder may not be able to interpret the output, resulting in a grade of 0.

One last XKCD comic for the quarter!
